EAGLE HARBOR TECHNOLOGIES

Introduction
Fast, reliable, real-time control of plasma is critical to the success of magnetic fusion science. High voltage and current supplies are needed to mitigate instabilities in all experiments as well as disruption events in large scale tokamaks for steady-state operation. Silicon carbide (SiC) MOSFETs offer many advantages over IGBTs, including lower drive energy requirements, lower conduction and switching losses, and higher switching frequency capabilities; however, these devices are limited to 1.2–1.7 kV devices. As fusion enters the long-pulse and burning plasma era, efficiency of power switching will be important. Eagle Harbor Technologies (EHT), Inc., developing a high voltage SiC MOSFET module that operates at 10 kV. This switch module utilizes EGT gate drive technology, which has demonstrated the ability to increase SiC MOSFET switching efficiency. The module will allow more rapid development of high voltage switching power supplies at lower cost necessary for the next generation of fast plasma feedback and control. EHT is partnering with the High Beta Tokamak group at Columbia to develop detailed high voltage module specifications, to ensure that the final product meets the needs of the fusion science community.

Integrated Power Module
The Integrated Power Module (IPM) is complete IGBT switch solution originally designed for magnet control. The EHT IPM includes fiber optically isolated gate drive, solid-state switches, freewheeling diodes, fast capacitors, snubbers (optional), and crowbar diodes (optional). This rack mount unit is easily integrated with customer DC supplies, capacitors, and loads.

Left: New EHT Integrated Power Module. Right: Switching profile of Integrated Power Module for 370 A at 1 kV at 125 MHz. RI shows V_s, CI shows V_s.
These units have been used to drive magnetic field coils both in and outside of the fusion science community:
• Pulsed magnet driver example: 2.5 kA at 100 kHz and 50% duty cycle for 10 ms
• Continuous magnet current: 500 A at 30 kHz and 50% duty cycle

The EHT IPM uses off-the-shelf discrete components, which simplifies and reduces costs. This allows us to take advantage of new advances in components, including IGBTs, without having to redesign the board. As designed today, the IPM has an absolute maximum voltage of 1200 V with a recommended maximum operating voltage of 800 V, which is suitable for many applications.

High Voltage for Fast Magnet Control
Fast changes in magnetic field are important to a variety of plasma control schemes. In order to enable faster magnet field changes, higher voltages are required. Quickly changing large current in coils requires voltages above 1200 V. High voltage IGBTs are available on the market today; however, SiC MOSFETs with voltages above 1200 V are not.

The time required to change the current in a coil with a 1 mH inductance,

Why SiC MOSFETs?
Advantages of SiC MOSFETs over Si MOSFETs and IGBTs:
• Minimized conduction losses produce a forward drop of ~2 V at 20 A
• Reduced switching losses
• Lower capacitance due to high current density and small die size.
• Operation at 2–5 times the switching frequencies than IGBTs.
• Lowest gate drive energy (QG<100 nC) across the recommended input voltage range.
• Lower operating temperatures due to higher component efficiency.
• Ultra-low leakage current (<1 mA).

Development Plan for HV SiC MOSFET Module
The primary goal of the Phase I program is to develop a proof-of-concept (POC) fast, high voltage switch module to eliminate the complexity of developing high voltage power systems while taking advantage of the efficiency gains of SiC MOSFETs. This module will be able to switch at 10 kV at 500 kHz for 10 ms. The ultimate current carrying capability will depend on the SiC MOSFET devices selected, but the target is ~100 A. The HBT-EP group at Columbia University will play a critical role in setting up the design specifications during the initial design phase to ensure that the final module meets the needs of the Validation Platform Experiments.

1. Design High Voltage Switch Module
a. Develop HV switch module specifications document
b. Perform SPICE modeling of HV switch module
c. Select electronic components for HV switch module
d. Design HV switch module circuit board

2. Build and Test High Voltage Switch Module
a. Procure electronic components
b. Assemble HV switch modules
b. Bench test HV switch module to show high power operation

3. Demonstrate Parallel Operation
a. Build test setup for parallel operation
b. Test multiple modules operating in parallel
b. Conduct fault tolerance and jitter testing

4. Prepare for Demonstration at HBT-EP During Phase II
a. Develop preliminary design for Phase II HV switch module
b. Consult with Columbia HBT-EP for Phase II system design

Conclusion
As fusion enters the long-pulse and burning plasma era, overall efficiency of power switching will become important. Currently, HV IGBTs allow for fast switching of large currents; however, future experiments will need to take advantage of the latest gains in power electronics and therefore require high voltage SiC MOSFET. There are currently no HV SiC MOSFETs on the market today. To meet the needs of future experiments, Eagle Harbor Technologies is developing a high voltage SiC MOSFET module that will allow for faster changes in large current in electromagnets. These units will allow for faster feedback and control of magnetic systems, thereby allow for greater plasma control.
